Training vs Testing

Testing:

$$P[|E_{\text{in}} - E_{\text{out}}| > \varepsilon] \leq 2e^{-2\varepsilon^2 N}$$

Training:

$$P[|E_{\text{in}} - E_{\text{out}}| > \varepsilon] \leq 2Me^{-2\varepsilon^2 N}$$

Training vs Testing

Testing:

$$P[|E_{\text{in}} - E_{\text{out}}| > \varepsilon] \leq 2e^{-2\varepsilon^2 N}$$

Training:

$$P[|E_{\text{in}} - E_{\text{out}}| > \varepsilon] \leq 2Me^{-2\varepsilon^2 N}$$

We would like to replace M by a quantity that is not useless with an infinite hypothesis set.

Review

The statement we would like to make is

$\mathbb{P}[|E_{\text{in}}(g) - E_{\text{out}}(g)| > \epsilon]$ is small for the final hypothesis g .

We know that

$$|E_{\text{in}}(g) - E_{\text{out}}(g)| > \epsilon$$

$$|E_{\text{in}}(h_1) - E_{\text{out}}(h_1)| > \epsilon$$

$$\text{or } |E_{\text{in}}(h_2) - E_{\text{out}}(h_2)| > \epsilon$$

...

$$\text{or } |E_{\text{in}}(h_M) - E_{\text{out}}(h_M)| > \epsilon$$

Overlap between bad events

Where did the M come from?

The \mathcal{B} ad events \mathcal{B}_m are

$$|E_{\text{in}}(h_m) - E_{\text{out}}(h_m)| > \epsilon$$

The union bound:

$$\mathbb{P}[\mathcal{B}_1 \text{ or } \mathcal{B}_2 \text{ or } \cdots \text{ or } \mathcal{B}_M]$$

$$\leq \underbrace{\mathbb{P}[\mathcal{B}_1] + \mathbb{P}[\mathcal{B}_2] + \cdots + \mathbb{P}[\mathcal{B}_M]}_{\text{no overlaps: } M \text{ terms}}$$

Can we improve on M ?

What is E_{out} ? What is E_{in} ?

What is E_{out} ? E_{in} ?

Consider another (very similar) hypothesis. How will E_{out} and E_{in} change?

- ΔE_{out} is the change in E_{out} (yellow area)
- ΔE_{in} is the change in labels of data points
- $|E_{\text{in}}(h_1) - E_{\text{out}}(h_1)| > \varepsilon$ happens as often as $|E_{\text{in}}(h_2) - E_{\text{out}}(h_2)| > \varepsilon$

Can we improve on M ? Yes, bad events are very overlapping!

The break point

What can we replace M with?

What can we replace M with?

What can we replace M with?

Instead of the whole input space, we consider a (finite) set of input points, and count the number of **dichotomies**.

The number of dichotomies is a candidate for replacing M .

What can we replace M with?

What can we replace M with?

Dichotomies and growth function

Examples of growth functions

The break point

Dichotomies: mini-hypotheses

- A hypothesis $h : \mathcal{X} \rightarrow \{-1, +1\}$
- A **dichotomy** $h : \{\mathbf{x}_1, \dots, \mathbf{x}_N\} \rightarrow \{-1, +1\}$

Let $\mathbf{x}_1, \dots, \mathbf{x}_N \in \mathcal{X}$. The dichotomies generated by \mathcal{H} on these points are defined by

$$\mathcal{H}(\mathbf{x}_1, \dots, \mathbf{x}_N) = \{(h(\mathbf{x}_1), \dots, h(\mathbf{x}_N)) \mid h \in \mathcal{H}\}.$$

For any \mathcal{H} , $\mathcal{H}(\mathbf{x}_1, \dots, \mathbf{x}_N) \subseteq \{-1, +1\}^N$ (the set of all possible dichotomies on any N points).

The number of dichotomies is at most 2^N :

$$|\mathcal{H}(\mathbf{x}_1, \dots, \mathbf{x}_N)| \leq |\{-1, +1\}^N| \leq 2^N.$$

The number of dichotomies is a candidate for replacing M .

The growth function

The growth function counts the most dichotomies on any N points:

$$m_{\mathcal{H}}(N) = \max_{\mathbf{x}_1, \dots, \mathbf{x}_N \in \mathcal{X}} |\mathcal{H}(\mathbf{x}_1, \dots, \mathbf{x}_N)|$$

The growth function satisfies:

$$m_{\mathcal{H}}(N) \leq 2^N.$$

If \mathcal{H} is capable of generating all possible dichotomies on $\mathbf{x}_1, \dots, \mathbf{x}_N$, then $\mathcal{H}(\mathbf{x}_1, \dots, \mathbf{x}_N) = \{-1, 1\}^N$ and we say that \mathcal{H} can **shatter** $\mathbf{x}_1, \dots, \mathbf{x}_N$.

$m_{\mathcal{H}}(N)$ is also known as the N -th **shattering coefficient** of \mathcal{H} .

The growth function for the perceptron ($N = 3$)

$$m_{\mathcal{H}}(3) = ?$$

The growth function for the perceptron ($N = 3$)

The growth function for the perceptron ($N = 4$)

$$m_{\mathcal{H}}(4) = ?$$

The growth function for the perceptron ($N = 4$)

The growth function for the perceptron

Applying $m_{\mathcal{H}}(N)$ definition - perceptrons

$N = 3$

$N = 3$

$N = 4$

$$m_{\mathcal{H}}(3) = 8$$

$$m_{\mathcal{H}}(4) = 14$$

Table of contents

Infinite hypothesis set: can we improve on M ?

What can we replace M with?

Dichotomies and growth function

Examples of growth functions

The break point

Example 1: positive rays

$$h(x) = \text{sign}(x - a)$$

$$m_{\mathcal{H}}(N) = ?$$

Example 1: positive rays

Example 1: positive rays

\mathcal{H} is set of $h: \mathbb{R} \rightarrow \{-1, +1\}$

$$h(x) = \text{sign}(x - a)$$

$$m_{\mathcal{H}}(N) = N + 1$$

Example 2: positive intervals

$$m_{\mathcal{H}}(N) = ?$$

Example 2: positive intervals

Example 2: positive intervals

\mathcal{H} is set of $h: \mathbb{R} \rightarrow \{-1, +1\}$

Place interval ends in two of $N + 1$ spots

$$m_{\mathcal{H}}(N) = \binom{N+1}{2} + 1 = \frac{1}{2}N^2 + \frac{1}{2}N + 1$$

Note that $m_{\mathcal{H}}(N)$ grows as the square of N , faster than the linear $m_{\mathcal{H}}(N)$ of the “simpler” positive ray case.

Example 3: convex sets

- \mathcal{H} consists of all hypotheses in two dimensions $h : \mathbb{R}^2 \rightarrow \{-1, +1\}$ that are positive inside some convex set and negative elsewhere.
- A set is convex if the line segment connecting any two points in the set lies entirely within the set.

Example 3: convex sets

- \mathcal{H} consists of all hypotheses in two dimensions
 $h : \mathbb{R}^2 \rightarrow \{-1, +1\}$ that are positive inside some convex set
and negative elsewhere.
- A set is convex if the line segment connecting any two points
in the set lies entirely within the set.

Example 3: convex sets

Example 3: convex sets

- Because we chose the N points at random in the plane, many of the points are “internal”, and we are not able to shatter all the points with convex hypotheses.
- Is there another choice for the points that provide more hypotheses?

Example 3: convex sets

Example 3: convex sets

Example 3: convex sets

Example 3: convex sets

Example 3: convex sets

\mathcal{H} is set of $h: \mathbb{R}^2 \rightarrow \{-1, +1\}$

$h(\mathbf{x}) = +1$ is convex

$$m_{\mathcal{H}}(N) = 2^N$$

The N points are 'shattered' by convex sets

The 3 growth functions

The 3 growth functions

- \mathcal{H} is positive rays:

$$m_{\mathcal{H}}(N) = N + 1$$

- \mathcal{H} is positive intervals:

$$m_{\mathcal{H}}(N) = \frac{1}{2}N^2 + \frac{1}{2}N + 1$$

- \mathcal{H} is convex sets:

$$m_{\mathcal{H}}(N) = 2^N$$

→ More complex \mathcal{H} gives a bigger growth function

Back to the big picture

$$P[|E_{\text{in}} - E_{\text{out}}| > \varepsilon] \leq 2M e^{-2\varepsilon^2 N}$$

In future lectures, we will see that $m_{\mathcal{H}}(N)$ can replace M . Our bound is now finite even for an infinite hypothesis set!

As a function of N , what is a good property of $m_{\mathcal{H}}(N)$?

Back to the big picture

$$P[|E_{\text{in}} - E_{\text{out}}| > \varepsilon] \leq 2M e^{-2\varepsilon^2 N}$$

In future lectures, we will see that $m_{\mathcal{H}}(N)$ can replace M . Our bound is now finite even for an infinite hypothesis set!

As a function of N , what is a good property of $m_{\mathcal{H}}(N)$?

If $m_{\mathcal{H}}(N)$ is polynomial (in N), this is good for learning!

In fact, for any real constants a and b such that $a > 1$,

$$\lim_{N \rightarrow \infty} \frac{N^b}{a^N} = 0.$$

We will prove that $m_{\mathcal{H}}(N)$ is polynomial. The key notion to do that is the **break point**.

What can we replace M with?

Dichotomies and growth function

Examples of growth functions

The break point

Main result

Main result

No break point $\implies m_{\mathcal{H}}(N) = 2^N$

Any break point $\implies m_{\mathcal{H}}(N)$ is **polynomial** in N

The break point

Break point of \mathcal{H}

Definition:

If no data set of size k can be shattered by \mathcal{H} , then k is a break point for \mathcal{H}

$$m_{\mathcal{H}}(k) < 2^k$$

For 2D perceptrons, $k = 4$

A bigger data set cannot be shattered either

In general, it is easier to find a break point for \mathcal{H} than to compute the full growth function for that \mathcal{H} .

Break point - the three examples

The 3 growth functions

- \mathcal{H} is positive rays:

$$m_{\mathcal{H}}(N) = N + 1$$

- \mathcal{H} is positive intervals:

$$m_{\mathcal{H}}(N) = \frac{1}{2}N^2 + \frac{1}{2}N + 1$$

- \mathcal{H} is convex sets:

$$m_{\mathcal{H}}(N) = 2^N$$

Is there a break point? What is it?

Break point - the three examples

Break point - the 3 examples

- Positive rays $m_{\mathcal{H}}(N) = N + 1$

break point $k = 2$

- Positive intervals $m_{\mathcal{H}}(N) = \frac{1}{2}N^2 + \frac{1}{2}N + 1$

break point $k = 3$

- Convex sets $m_{\mathcal{H}}(N) = 2^N$

break point $k = \infty$

Main result

No break point $\implies m_{\mathcal{H}}(N) = 2^N$

Any break point $\implies m_{\mathcal{H}}(N)$ is **polynomial** in N

A puzzle ($N = 3$)

Let us assume $k = 2$ is a break point. What are the number of dichotomies on $N = 3$ points? (Use \circ for -1 and \bullet for $+1$).

$$\underline{\mathbf{x}_1 \quad \mathbf{x}_2 \quad \mathbf{x}_3}$$
